NOVAFRICA is a knowledge center created by the Nova School of Business and Economics of the Nova University of Lisbon. Its mission is to produce distinctive expertise on business and economic development in Africa. A particular focus is on Portuguese-speaking Africa, i.e., Angola, Cape Verde, Guinea-Bissau, Mozambique, and Sao Tome and Principe. The Center aims to produce knowledge and disseminate it through research projects, publications, policy advice, seminars, conferences and other events.

NOVAFRICA Working Papers often represent preliminary work and are circulated to encourage discussion. Citation of such a paper should account for its provisional character. A revised version may be available directly from the author.

Adopting Mobile Money: Evidence From An Experiment In Rural Africa

By CATIA BATISTA AND PEDRO C. VICENTE *

January 2020

Abstract

Who uses mobile money? And what is mobile money used for? This paper describes the mobile money adoption patterns following the experimental introduction of mobile money services for the first time in rural areas of Southern Mozambique. In particular, we examine the individual characteristics of early and late adopters, as well as their mobile money usage patterns. For this purpose, we use a combination of administrative and household survey data to characterize the adoption of mobile money services in the three years following their initial introduction. We find that a large proportion of the individuals who were offered mobile money services adopted this technology. These users of mobile money (and early adopters in particular) are more educated than non-users, and they also are more likely to already hold a bank account. Positive-self-selection into mobile money usage raises the question of whether mobile money is an effective tool for financial inclusion.

Vicente: Nova School of Business and Economics, Universidade Nova de Lisboa, Campus de Carcavelos, Rua da Holanda N. 1, Lisboa, Portugal (e-mail: pedro.vicente@novasbe.pt). We gratefully acknowledge funding from the UKAid-funded IGC, the Portuguese National Science Foundation (Grants PTDC/IIM-ECO/4649/2012 and UID/ECO/00124/2013), the UKAid/IZA GLM-LIC program, and NOVAFRICA at the Nova School of Business and Economics. We are particularly indebted to our partner Carteira Móvel for a fruitful collaboration. This article is the result of exhaustive work by a large team of people at NOVAFRICA to whom we are indebted.

Mobile money creates the opportunity for individuals with basic cell phones in poor areas underserved by formal financial services to save and receive long distance transfers instantly, safely and inexpensively.

Mozambique is a country with extremely limited financial inclusion even by sub-Saharan standards. According to Demirgüç-Kunt et al. (2018), in 2017 only 10% of adults living in rural areas of the country held savings in a formal bank account. And only 15% of migrant remittances were received via formal channels in these rural locations.

We conducted a randomized controlled trial to investigate the impact of introducing mobile money services for the first time in rural areas of Southern Mozambique. In this paper we describe the mobile money adoption patterns following this intervention. Batista and Vicente (2013) describe the randomized introduction of mobile money in detail, whereas Batista and Vicente (2018) examine the economic impact of this randomized controlled trial.

This article describes the individual characteristics of early and late adopters and examines their mobile money usage patterns. We use a combination of administrative and household survey data to characterize the adoption of mobile money services in the three years following their initial introduction.

A large proportion of the sampled individuals who were offered mobile money services adopted this technology. These users of mobile money (and early adopters in particular) are likely to be more educated than non-users, and they also are more likely to already hold a bank account. These findings are in line with Suri (2011) in that education and financial inclusion are both associated with lower costs of using mobile money technology. Education in particular is also possibly linked with higher potential benefits of mobile money – especially when this technology is used to receive remittances from migrants who also tend to be positively selected on education.

Positive-self-selection into mobile money usage raises the question of whether mobile money is an effective tool for financial inclusion. Indeed, if those who adopt mobile money first and keep using this technology over time are disproportionately those who already had bank accounts, this is an effective tool for financial deepening – and new approaches to promote financial inclusion must be devised together with strategies for organic technology adoption following its initial dissemination.

I. Sampling and Data

Our work builds on a large randomized controlled trial by Batista and Vicente (2018). This project evaluated the economic impact of randomly introducing mobile money services for the first time in rural areas of Southern Mozambique.

As described in detail by Batista and Vicente (2013), mobile money was introduced in 51 enumeration areas (EAs) that were followed over time using household surveys and administrative data. The baseline household survey, performed before mobile money was made available, provides us with the baseline characteristics of all the individuals who were offered the mobile money technology in the treated areas. The administrative data on mobile money usage were provided by *Carteira Movel*, the operator of the *mKesh* mobile money brand in Mozambique. These data allow us to characterize the timing and type of mobile money operations being conducted by users between July 2012 and June 2015.

II. Who Are the Adopters?

The measured adoption rate for mobile money in this project was large: 87 percent of the individuals offered mobile money services made at least one transaction over the three-year period for which we have administrative records. As shown in Table 1, 36 percent of our sample are *Early Adopters* who start using the service from its inception and keep on doing so in the following three years, whereas 18 percent are *Experimenters* - i.e. users in the first year who stop making transactions afterwards. *Late Adopters*, who only start using mobile money in the second or third year after it was made available, are 6 percent of our sample.

Table 1 shows the characteristics of adopters in our sample. Users of mobile money are positively self-selected. They are significantly more educated than non-users and are also significantly more likely to have a bank account of their own, to have a job and to be wage earners. This positive self-selection pattern is reinforced for *Early Adopters*: these early and continued users of mobile money have an average additional year of schooling (relative to non-*Early Adopters*) and they are 13 percentage points more likely to hold their own bank account. *Early Adopters* are also more likely to have jobs and be wage earners than average users.

Note: "Users" have at least one transaction recorded in the administrative data. "Early adopters" are defined as users of mobile money in all three years covered by data. "Experimenters" are defined as users of mobile money in the first year after its introduction, but not in subsequent years. "Late Adopters" are defined as users of mobile money who only started using the service in the second or third years after its availability. Statistical significance is assessed on the estimated difference between mean utilization rates of adopters and non-adopters in the full sample, for each definition of adopter. Estimated difference is not shown. † significant at 15%; * significant at 10%; ** significant at 5%; *** significant at 1%.

Experimenters who used the service early on and afterwards stopped using it are not positively selected from the full sample. They are marginally less likely to own a bank account and more likely to have a car – which may enable them to travel to nearby urban areas and make use of formal financial services (e.g. to send remittances) at a lower cost than other residents in rural areas. *Late Adopters* cannot be statistically distinguished from other individuals in the full sample.

Interestingly, unlike prior work on mobile phone and mobile money technology adoption, such as Aker and Mbiti (2010) or Jack and Suri (2011), respectively, we do not find any evidence that users are statistically different from non-users in terms of age, gender or expenditure profile.

III. What Do Adopters Do?

In order to understand the incidence of each type of transaction made by the different mobile money users, we estimate the following regression:

$$(1) Y_{il} = \alpha + \beta_1 \text{EarlyUser}_{il} + \beta_2 \text{Experimenter}_{il} + \beta_3 \text{LateUser}_{il} + \gamma X_i + \theta_l + \varepsilon_{il}$$

where Y_{il} is the outcome variable of interest for household i in location l ; EarlyUser_{il} equals one if individual i has a recorded transaction in all three years in the administrative dataset; Experimenter_{il} equals one if individual i has a recorded transaction in the first year after mobile money is introduced but not in any of the subsequent years; LateUser_{il} equals one if individual i does not have a recorded transaction in the first year after mobile money is introduced, but as recorded transactions in any of the later years; X_i is a vector of individual controls including demographics and financial indicators; and θ_l is a vector of location fixed effects.

Table 2 describes the predictors of each type of mobile money transaction being performed. As could be expected, *Early Adopters* are more likely to perform all transactions, but they are especially prone to receive and send transfers, as well as to purchase airtime. *Experimenters*, in contrast, are more likely to purchase airtime and less likely to receive transfers. *Late Adopters* tend to receive and send less transfers than all other mobile money users in the sample – this is consistent with their lack of initial adoption, unlike that of *Early Adopters* that seem to base their continued adoption on transfer activity.

Table 3 shows that the average value per mobile money transaction is again higher for all transactions performed by *Early Adopters* relative to all other mobile money users in the sample. These average values are particularly higher for transfers received and cash-outs – a pattern consistent with individuals who often receive transfers from migrants in urban areas – in line with the results discussed by Batista and Vicente (2018). On the contrary, *Experimenters* tend to have lower average values of cash-outs and transfers received, whereas *Late Adopters* display lower average values of transfers sent.

IV. Concluding Remarks

Our analysis shows that adoption of mobile money tends to be positively self-selected. Early adopters in rural areas who continuously use the technology (and receive most remote transfers) are better educated and often already own a bank account. Spreading further the financial inclusion benefits of mobile money requires designing technology dissemination strategies that go beyond the financial literacy, free experimentation and in-person support provided by the experimental intervention we implemented.
